Module 1 Cheat Sheet: Python Basics

Package/Method	Description	Code Example
		1. 1
Comments	Comments are lines of text that are ignored by the Python interpreter when executing the code<./td>	1. # This is a comment Copied!
		Syntax: 1. 1 1. concatenated_string = string1 + string2
Concatenation	Combines (concatenates) strings.	Copied! Example: 1. 1
		1. result = "Hello" + " John" Copied! Example:
Data Types	- Integer - Float - Boolean - String	1. 1 2. 2 3. 3 4. 4 5. 5 6. 6 7. 7 8. 8 9. 9 10. 10
		1. X=7 2. # Integer Value 3. y=12.4 4. # Float Value 5. is_valid = True 6. # Boolean Value 7. is_valid = False 8. # Boolean Value 9. F_Name = "John" 10. # String Value
Indexing	Accesses character at a specific index.	Copied! Example: 1. 1 2. 2 1. my_string="Hello"
		2. char = my_string[0] Copied! Syntax: 1. 1 1. len(string_name)
len()	Returns the length of a string.	Copied! Example:
		<pre>1. 1 2. 2 1. my_string="Hello" 2. length = len(my_string)</pre>
		Copied! Example: 1. 1
lower()	Converts string to lowercase.	<pre>1. 1 2. 2 1. my_string="Hello" 2. uppercase_text = my_string.lower()</pre>
print()	Prints the message or variable inside `()`.	Copied! Example:
		1. 1 2. 2

about:blank 1/3

7/8/24, 12:57 PM about:blank

```
    print("Hello, world")

                                                                                                       print(a+b)
                                                                                                     Copied!
                                                                                                    Example:
                                                                                                       1. 1
                                                                                                      2. 2
3. 3
                                                                                                       4.4
                    - Addition (+): Adds two values together.
                                                                                                       5. 5
                    - Subtraction (-): Subtracts one value from another.
                                                                                                       6.6
                    - Multiplication (*): Multiplies two values.
Python Operators
                    - Division (/): Divides one value by another, returns a float.
                                                                                                       1. x = 9 y = 4
                    - Floor Division (//): Divides one value by another, returns the quotient as an \,
                                                                                                       2. result_add= x + y # Addition
                                                                                                       3. result_sub= x - y # Subtraction
4. result_mul= x * y # Multiplication
5. result_div= x / y # Division
                    - Modulo (%): Returns the remainder after division.
                                                                                                      6. result_fdiv= x // y # Floor Division
7. result_mod= x % y # Modulo
                                                                                                    Copied!
                                                                                                    Example:
                                                                                                       2. 2
replace()
                    Replaces substrings.

    my_string="Hello"

                                                                                                       2. new_text = my_string.replace("Hello", "Hi")
                                                                                                     Copied!
                                                                                                    Syntax:
                                                                                                       1. 1
                                                                                                       1. substring = string_name[start:end]
                                                                                                     Copied!
Slicing
                    Extracts a portion of the string.
                                                                                                    Example:
                                                                                                      1. 1
                                                                                                       1. my_string="Hello" substring = my_string[0:5]
                                                                                                    Copied!
                                                                                                    Example:
                                                                                                       1. 1
                                                                                                       2. 2
                    Splits string into a list based on a delimiter.
split()

    my_string="Hello"

                                                                                                       2. split_text = my_string.split(",")
                                                                                                    Copied!
                                                                                                    Example:
                                                                                                       2. 2
strip()
                    Removes leading/trailing whitespace.
                                                                                                       1. my_string="Hello"
                                                                                                       2. trimmed = my_string.strip()
                                                                                                     Copied!
                                                                                                    Example:
                                                                                                       1. 1
                                                                                                       2. 2
upper()
                    Converts string to uppercase.
                                                                                                       1. my string="Hello"
                                                                                                       2. uppercase_text = my_string.upper()
                                                                                                     Copied!
Variable
                    Assigns a value to a variable.
                                                                                                    Syntax:
Assignment
                                                                                                       1. variable_name = value
                                                                                                     Copied!
                                                                                                    Example:
                                                                                                       2. 2
                                                                                                       1. name="John" # assigning John to variable name
```

7/8/24, 12:57 PM about:blank

2. x = 5 # assigning 5 to variable x
